Build a Tower Crane: A STEM Challenge!

Have you ever seen a crane? These tall cranes, usually seen on large construction sites, can lift very heavy loads. Want to know how they work? Make this fun tower crane craft and learn some simple facts about the science and engineering principles behind them, as well as how to move and place heavy objects yourself.

- Age: 9-12
- Time: about 2 hours
- Steve Lovell Verney

Materials Needed:

Two cups
Small bucket
Paper tape
Masking tape
Plastic bottle with cap
White glue
Pen or pencil
Yarn
Toothpicks
Paper clip
Scissors
Wooden sticks
Paint brush
Acrylic paint
Paintbrush
Cardboard

Step-by-Step Instructions:

1. Cut the cardboard as shown in the diagram below. The drawn shape will become one side of the crane's jib.

2. Be diligent in the diagram below, draw dots at regular intervals along the edges, adding a dot in the middle of the rectangular part.

3. Push toothpicks through each small dot, with clay, underneath the cardboard to protect the table and your fingers.

Before adding glue, the friction between the toothpicks and cardboard will hold the toothpicks in place.

4. Apply white glue to the tips of the toothpicks, doing one side first and waiting for the glue to dry before doing the other side.

5. Cut out corresponding areas of cardboard to make the base of the triangular rail

6. Turn the triangular rail upside down, apply glue to the short horizontal edge, press the rectangular cardboard in the appropriate position, and wait for the glue to dry.

7. Use clay to form small balls covering both ends of each toothpick to ensure no sharp points protrude from the triangular rail.

8. Make the crane's handle by drawing and cutting out two circular pieces using a bottle cap. Using a needle, stitch a yarn a hole in each circular piece, with an extra hole on the edge of one of the circular pieces.

9. Cut out 8cm and 12cm wooden sticks, score with a pencil, then cut.

10. Insert the two wooden sticks into the circular piece with two holes, with the shorter stick going into the side hole.

11. Use white glue to attach the wooden sticks in place. The wooden sticks and cardboard pieces form a device called a crank, which you can use to lift loads.

12. Push the long wooden stick through the hole in the middle of the triangular part's rectangular part, coming out the other side. Glue the wound cardboard circle to the other end of the wooden stick.

13. Use acrylic paint to decorate your crane.

14. Turn the triangular rail upside down and glue the bottom of one of the cups to the base. Wait for the glue to dry.

15. Make two thick clay balls and clamp them onto the toothpicks at the back of the triangular rail.

16. Next, cut a piece of yarn, tie one end to the middle wooden stick and thread it through from the right side.

17. Fill the plastic bottle with water to prevent the crane from tipping over. Real cranes are anchored to heavy concrete bases for stability, and bottled water is heavy and cheap.

18. Use paper tape to secure the second cup to the plastic bottle.

19. Place marbles inside the edge of the upturned cup base, ensuring there's enough space for the marbles to move slightly. The marbles will act as bearings in the machine, allowing other parts to rotate freely.

20. Mount the crane's jib on the tower by fitting the cardboard over the plastic bottle lattice.

21. Finally, balance the small container formed with the cargo inside it for the pilot.

22. Raise or lower it by turning the handle.

The Science Behind It:

Tower cranes can lift enormous loads without toppling because they use control torque. Torque is the rotational force produced by the crane's jib, and its magnitude is related to the position and weight of the load. The further the load is from the tower, the greater the torque, because torque equals the load weight multiplied by the distance from the tower. Cranes use counterweights to balance the torque from the load, technically making them (such as counterweights) counterforces (forces reversing, ensuring the crane's stability. When lifting larger loads, the crane's load closes to the tower, while smaller loads can be lifted at greater distances.

Test how much weight a crane can lift without tipping over. Try adjusting the distance of the rope from the tower and see how it affects the weight the crane can lift. What happens if you adjust the crane handle mechanism? Can you make it easier to lift heavier loads? Can you add changes to your crane that also increase or decrease the weight of the counterbalance?
